EXAMINATION OF CLAY SAMPLES
SUPPLIED BY DIVISION OF MINERAL RESOURCES

January 1970 Progress Report
Lab. No. 3518; A, B, C, D, & E - Book No. 261
by
Edwin H. Bentzen III

Introduction

In February 1969, five samples of white residual clay from the volcanic slate belt in North Carolina, were collected by the State Division of Mineral Resources, Raleigh. Samples from these locations had previously been submitted to the U. S. Bureau of Mines for testing. The Bureau gave potential uses for each sample; however, no uses were named which could be the basis for a large industry. (See Tables 1 through 10 for collection and testing data.) Later this year, portions of the resampled material were submitted to the Minerals Research Laboratory for preliminary beneficiation studies. The object of this work was to produce, by minimal processing, a product on which a larger scale industry might be based. The type products under consideration included ball clay, kaolinite clay, brick clay, sericite, and ceramic products.

Although three of the five materials sampled had been used as additives to brick clay, only one is in use as such today. Also, in each case they were minor constituents of a red brick, and not major constituents of a white brick.
Sample Identification

The five samples submitted were assigned Lab No. 3518, A through E. Cross identification with D.M.R. sample numbers is shown below:

<table>

</tbody>
</table>

Also see Tables 1, 3, 5, 7, and 9 for additional information.

Procedure

The samples were crushed through a roll crusher, set at \( \frac{1}{2} \) inch, mixed and sampled for chemical analysis. The complete chemical analyses are shown in Table 11. On the basis of the chemical analyses, and equations derived by Koenig* and Coffeen**, the following mineralogic compositions were projected:

</table>

The exact method used to determine the rational analysis is
given in Table 12.

The test procedure used to determine "grit" is an adaptation of
one explained in J. M. Huber Corporation publication, Kaolin Clays and
Their Industrial Uses. In place of a Hamilton-Beach mixer No. 18, a
Wemco Mineral Master with a small propeller and a 500-gram capacity
octagonal pot were used. The speed was adjusted to 2,000 R.P.M.

Tetrasodium pyrophosphate solution was made by dissolving 20 grams
of anhydrous tetrasodium pyrophosphate (\(\text{Na}_4\text{P}_2\text{O}_7\)) in 1,000 cubic centi-
meters of distilled water. One hundred grams of clay, 375 cubic centi-
meters of water and 25 cubic centimeters of tetrasodium pyrophosphate
solution were placed in the pot and mixed at high speed for ten minutes.
The mixture was poured slowly into an eight-inch diameter, 325 mesh
screen which had previously been wetted with water. The pot was washed
throughly, and the washings were poured onto the screen. Generally,
the chemical treatment indicated above was sufficient to produce free
screening. However, in cases where the screen became clogged because
of a high-viscosity clay or excessive residue, the screening was facil-
itated by directing a stream of water against the screen from a rubber
hose. The force of the water can be regulated by squeezing the end of
the rubber hose. The clay was washed through the screen with a stream
of water until the wash water was clear and free from clay particles.
This operation can be completed in one minute or less.

The residue on the screen was washed into a small pan and allowed
to stand for two to three minutes. The clean water was decanted by using
a glass stirring rod pressed against the lip of the pan. The residue
was dried in the pan at 105°C, cooled and weighed.

The minus 325 mesh slurry was collected in a 2½-gallon bucket which was filled to a depth of ten inches. The slurry was well mixed to place all solids in suspension, and was allowed to settle. After a specified amount of time, the suspended material was poured off. The sinks were collected, dried at 105°C, cooled and weighed. The suspended solids were either further settled for a specified time, or flocculated. Assay samples were collected and analysed. Figure No. 1 shows the weight percent settled out of the suspension as a cumulative percent (including the plus 325 mesh grit), versus time in minutes.

Using the information in Figure 1, in connection with other data, such as percent oversize, percent clay, percent mica, and percent wasted slimes (unsettled after 24 hours), a settling time was chosen for each sample. It was chosen in such a manner as to remove the maximum amount of sand and silt, and to segregate the maximum amount of kaolinite. Trial runs were undertaken using these settling times. The results of these runs can be seen in Table 13.

It had been agreed upon, with Mr. Conrad, that one pound of clay product would be produced for U.S.B.M. testing. From the test data, it was seen that 2,000 grams of head feed would have to be treated in order to produce the necessary weight of product.

Only the three higher-grade samples were treated to produce clay product. Each was treated as before. One hundred-gram samples were mixed with a pyrophosphate solution, screened, and settled to remove grit and silt. The slimes and clay were poured into a cut-off 55-gallon drum to a depth of ten inches. After mixing they were allowed to stand for 24 hours. The slimes were then siphoned off and discarded. The
clay product was dried at 105°C, cooled and weighed. The dried clay was screened on a 200 mesh screen, sampled for assay, and checked for color reflectance and bulk weight. The results can be seen in Table 14.

Results

The clay content of the head feed, as determined by a rational analysis, was rather disappointing, especially when compared to some deposits in South Carolina and Georgia. Some of the deposits worked for ball clay or kaolin contain 85 to 95 percent kaolinite. These deposits lend themselves to simple beneficiation with high yield. With the minimal processing used here, aimed at the best balance between maximum weight recovery and high grade clay, the yield was low. More rigorous processing could probably produce a better yield, however this would prove costly in production.

The color readings on the products were not as high as those necessary for paper or paint filler markets. The bulk weight, however, was in the right range.

It is hoped that more light can be shed on market possibilities when the results of U.S.B.M. test work is received.

Other Tests & Comments: Very short and fine, powders when dry. CaCO₃ (qual.): slight pos. Very weak at all temperatures.

Potential Uses: Non-plastic filler to modify shrinkage and color in brick and other S.C.P. If a D.T.A. indicates high kaolin, it might be used for whitewares. A high P.C.E. would indicate potential use in refractories.
